Runtime control signals: before and after mitigation

600 messages/s during evaluation | 80% of input to 12 of 60 partitions | 16 trials

Windows update every 2 seconds. Mean growth requires 16 observations; mean skew uses 15 observations spanning 28 seconds.
Ownership changes, missing data and excessive gaps reset affected windows. Unavailable values are not zero or interpolated.
Negative growth indicates decreasing backlog. Read skew alongside backlog size: high relative skew can remain when little work is queued.
